A linear two terminal circuit can be replaced by an equivalent circuit consisting of a voltage source  $V_t$  in series with a resistor  $R_t$  where  $R_t$  is the ratio of

1. open circuit voltage to the short circuit current at the terminal pair.
2. short circuit current to the short circuit voltage at the terminal.
3. Open circuit voltage to the open circuit current at the terminal pair.
4. the independent sources are turned off.

(A) 1 and 4

(B) 2 and 4

Consider a system with five processes P0 through P4 and three resource types R1, R2 and R3. Resource type R1 has 10 instances, R2 has 5 instances and R3 has 7 instances. Suppose that at time T0, the following snapshot of the system has been taken :

Assume that now the process P1 requests one additional instance of type R1 and two instances of resource type R3. The state resulting after this allocation will be

- (A) Ready State
- (B) Safe State
- (C) Blocked State
- (D) Unsafe State

A CPU has a 32 kB direct mapped cache with 128-byte block size. Suppose A is a two-dimensional array of size 512 x 512 with elements that occupy 8-bytes each.

Consider the following two C code segments, P1 and P2

```
P1 : for (i=0; i<512; i++ ) {  
    for (j=0; j<512; j++) {  
        X+ = A[i] [j];  
    }  
}
```

```
P2 : for(i=0; i<512; i++) {  
    for (j=0 ; j< 512; j ++ ) {  
        {X+ = A[j] [i];}  
    }  
}
```

P1 and P2 are executed independently with the same initial state, namely, the array A is not in the cache and i, j, x are in registers. Let the number of cache misses experienced by P1 be  $M_1$  and that for P2 be  $M_2$ .

The value of the ratio  $M_1/M_2$  is

- (A) 0
- (B) 1/6
- (C) 1/8
- (D) 16
